ABSTRACT

Nutritional Psychiatry is a term used to describe a field of research, and a way of approaching the prevention and treatment of mental illness, which focuses on diet and nutrition. Among the complexity of the determinants of Mental Health problems, the emerging evidence from Nutrition shows relevant factors in the high prevalence of mental disorders, suggesting that diet is as important for Psychiatry as for Cardiology and Endocrinology. Studies of the relationship between diet quality (and potential nutritional deficiencies) and mental health disorders, as well as the use of nutrients to treat deficiencies, are increasing. Nutritional psychiatry has been promoting the interaction between the cardiologist-nutritionist-neuroscientist, which has been recommended in the nutritional care of patients with chronic diseases, among them: heart failure. Certainly, this new area of nutritional psychiatry will allow us to broaden our look under the conception of future research that evaluates intervention in multidisciplinary and interdisciplinary approach.

INTRODUCTION

What's the evidence?

Nutritional psychiatry is a new area for the study of the correlation of mental disorders, metabolic abnormalities, nutrition in chronic diseases (1). The term "Nutritional Psychiatry" emerged in 2013 after a consensus statement that advocated as a new field of research focused on the comprehensive development of evidence, cohesive and scientifically rigorous to support a shift in thinking around the role of diet and nutrition in health (2). Nutritional psychiatry has been promoting the interaction between cardiologist-nutritionist-psychiatrist-neuroscientist, which has been recommended in the nutritional care of patients with chronic diseases, among them: heart failure (1-3). HF is a complex clinical syndrome, often chronic in nature, which is associated with metabolic, inflammatory, nutritional abnormalities and has a high prevalence of depression (1,4).

HF promotes metabolic and nutritional abnormalities that are associated with different multimorbidities, among them depression. Current evidence shows that better food quality, i.e. fruits, vegetables, fish and whole grains are associated with lower risk for depressive symptoms, but not all available results are consistent with the hypothesis that diet influences the risk to develop depression (3,5,6). Depression when associated with heart conditions causes inflammatory, metabolic and nutritional disorders. Lifestyle and particularly nutrition seem to be able to influence the development and course of depressive morbidity. Different nutrients or different dietary patterns can influence the aggravation of depressive symptoms, but are not yet explored in HF (1,2,7). Nutritional aspects are so important in mental health that they have inspired researchers to a new field of multidisciplinary research called nutritional psychiatry. The multidisciplinary approach involving nutritionist, psychiatrist, psychologist, neuroscientist and cardiologist specializing in HF has allowed a transdisciplinary look at the relationship in mind/brain and metabolism, lifestyle and nutrition in chronic diseases (7). The changes in the dietary pattern have been reported with the
worsening of depressive symptoms and depression, resulting in increased inflammation and oxidative stress, consequently in nutritional deficiencies and depletion of essential fatty acids. Nutrients form the substrate of essential biological processes in the body and brain, thus ensuring that nutrient levels are adequate in patients suffering from serious diseases is important (1,8). In the study conducted by Sarris et al., 2015 (3) in the area of nutritional psychiatry showed that patients who consumed foods rich in omega 3 or eicosapentaenoic acid (EPA) showed strong association in significantly reducing depressive symptoms. In addition, other studies alone showed that the benefits of creatine supplementation by adding zinc, vitamin C, the amino acid tryptophan and folic acid produced mixed results in depressed patients, however, considered all these supplements relatively safe. Although, it is not the focus of nutritional psychiatry to support the use of nutritional supplements. Jacka et al., 2017 have speculated that the use of these supplements can increase the effectiveness of antidepressants in various ways, perhaps directly altering the activity of neurotransmitters or indirectly, reducing inflammation, known to contribute to depression. However, research in this area is gradually uncovering potential facts based on their specific nutritional deficiencies, brain conditions and genetic profiles, seeking to understand the basic factors that can influence nutrient metabolism, including intestinal health. (1-5)

Currently, we have started in Brazil the pioneering research in the line of nutritional psychiatry in patients with heart failure, which is an innovation in the field of research, because in this study we think about mental and brain health and the relationship with cardiology, the model focused on integrative physiology, nutritional aspects and the understanding of biomarkers (7). Certainly, this new area of nutritional psychiatry will allow us to broaden our look under the design of future research that evaluates the intervention in mental health - nutrition - cardiology - facing a multi and interdisciplinary approach.
